CLIENT PITCH DECK

Reliable data foundations. Practical AI systems.

I help businesses modernise their data platforms, build reliable pipelines, and develop AI systems connected to real business workflows.

Faris Hussain
Data & AI Platform Engineer
Munich, Germany

THE PROBLEM

Your AI ambitions depend on your data foundations.

Business-critical data is often spread across disconnected systems, fragile pipelines, and legacy platforms.

Teams spend time reconciling numbers instead of using them. AI prototypes add another layer of complexity when the underlying data is difficult to access or trust.

> The challenge is not adding more tools. It is making the system work together.

THE APPROACH

Connect the foundation to the business outcome.

1

Build the foundation

Bring operational data into a consistent, usable platform.

2

Make it dependable

Establish orchestration, quality checks, clear access, and operational ownership.

3

Put it to work

Enable analytics, business integrations, and carefully evaluated AI applications.

One connected approach — from source systems to the people and applications that use the data.

• ABOUT ME

Architecture thinking. Hands-on engineering.

Architecture decisions translated into working data and AI systems.

- Munich-based Data & AI Platform Engineer.
- Energy trading, insurance, finance, and data-platform products.
- Warehouse modelling, cloud ingestion, orchestration, access governance, and multi-agent AI research.

WORKED WITH

Enmacc GmbH Royal Cyber Inc. Astera Software Syssoft Solutions Inc. HBA Basel-Landschaft Brokrly Team

Working style: hands-on implementation and clear trade-offs for technical and business stakeholders.

SERVICES

Three ways I can help.

Data platform modernisation

Assess existing architecture, design the target platform, and plan migrations around business priorities.

Reliable data engineering

Build and improve ingestion, transformations, orchestration, and governed data delivery.

AI systems & evaluation

Develop domain-specific agents and integrations, then evaluate their behaviour against clear baselines.

Each engagement starts with a defined problem and agreed acceptance criteria.

OFFERING · 01

Modernise with a clear migration path.

A phased migration built around business priorities.

- Assess the current architecture and dependencies.
- Design warehouse or lakehouse foundations, including Data Vault 2.0.
- Plan multi-source, legacy-to-cloud delivery with reconciliation and cutover criteria.

Typical deliverables: architecture diagrams, decision records, a migration roadmap, and scoped implementation.

OFFERING · 02

Build dependable data delivery.

Reliable pipelines, not just data in storage.

- Connect APIs and operational systems to cloud storage, catalogues, analytics, and consumers.
- Use incremental processing, stable schemas, and orchestration.
- Make retries, useful alerts, and recovery part of operational handover.

Typical deliverables: working pipelines, orchestration, validation checks, infrastructure as code, and operational handover.

OFFERING · 03

Give AI a bounded, testable role.

Establish where an agent helps before expanding its responsibility.

- Define a bounded workflow and explicit tool access.
- Compare agent behaviour with rule-based alternatives where appropriate.
- Evaluate against measurable criteria and observed behaviour.

Typical deliverables: a scoped prototype, system integrations, an evaluation framework, and recommendations grounded in observed behaviour.

• SELECTED DELIVERY

Finance data ready for analytics.

Finance and CRM data made available for reporting and planning.

Conceptual delivery flow — simplified from the completed scope

SOURCE

Finance APIs

Required source datasets identified and validated.

→

MY IMPLEMENTATION

Incremental ingestion

API-to-cloud pipeline, productionised and scheduled.

→

ANALYTICS ACCESS

Queryable datasets

Finance data available in the cloud analytics environment.

Delivered: scheduled finance ingestion and queryable finance/CRM datasets. Stakeholders confirmed the required queries were usable.

Scope boundary: ingestion completed; downstream planning-platform integration is a separate, ongoing phase.

• SELECTED DELIVERY

Make the current architecture clear.

Due diligence grounded in evidence, not a mix of current capabilities and future plans.

Conceptual assessment workflow — not a client architecture diagram

EVIDENCE INPUTS

Repository documentation

Read-only cloud discovery

→

MY ASSESSMENT

Current-state baseline

Reconcile sources, map architecture, and identify gaps.

→

DECISION SUPPORT

Current vs. target

Separate existing capabilities from future plans.

Delivered: a reviewed architecture baseline, current-to-target comparison, and traceable stakeholder-facing slides.

Evidence boundary: assumptions and unknowns are explicit; future plans are not presented as current capabilities.

• SELECTED RESEARCH

Multi-agent energy trading.

How do LLM-driven agents compare with rule-based alternatives in simulated negotiation?

Conceptual experiment design — no measured results depicted

SIMULATION INPUTS

Energy-domain data

Data-to-simulation transformations; baseline and stress scenarios.

→

LLM-driven agents

Buyer / seller negotiation

Rule-based alternatives

Comparison baseline

→

EVALUATION

Experiment analytics

Negotiation outcomes, economic measures, and model telemetry.

My contribution: energy-specific agents, data transformations, negotiation workflows, and experiment analytics.

Research only: simulated workflows, not live autonomous trading or a claim of commercial returns.

BEYOND THE DEMO

Engineering beyond the happy path.

My wider experience includes:

Platform operations

Improving ingestion continuity, Airflow logging, notifications, and failure visibility.

Governed access

Contributing to data classification, managed access, and infrastructure-as-code adoption.

Reusable data products

Contributing to metadata-driven warehouse tooling and API integration features.

The goal is not just a working demonstration. It is a system another team can understand, use, and maintain.

HOW WE'D WORK

Visible checkpoints, from scope to handover.

1

Discover

Understand the problem, systems, constraints, and stakeholders.

Checkpoint: shared problem

2

Define

Agree scope, deliverables, architecture, and acceptance criteria.

Checkpoint: agreed scope

3

Build

Review increments, dependencies, and trade-offs as implementation progresses.

Checkpoint: reviewed work

4

Validate & hand over

Check behaviour, document limitations, and establish operational ownership.

Checkpoint: accepted delivery

Progress is measured against accepted deliverables — not just activity.

• ENGAGEMENT OPTIONS

Choose a starting point.

ENGAGEMENT	BEST FOR	START WITH	TYPICAL OUTPUT
Architecture assessment	Clarity before migration or platform investment.	Current systems, dependencies, and constraints.	Architecture baseline and migration roadmap.
Scoped implementation	A defined pipeline, integration, modernisation, or AI need.	A bounded problem and acceptance criteria.	Working implementation, validation, and handover.
Technical advisory	Architecture decisions, reviews, or delivery planning.	A decision to make or implementation to review.	Decision records and implementation recommendations.

Scope, timeline, availability, and fees are agreed after an initial discussion.

• NEXT STEP

Let's define the right next step.

Modernising a data platform?

Connecting fragmented business systems?

Evaluating where AI can genuinely help?

Start with a conversation about the problem, the constraints, and what a useful outcome would look like.
